[FILL IN YOUR NAME]

[FILL IN THE DATE]

## Assignment 1: Using mixed effects modelling to model hierarchical data

In this assignment we will be investigating the *politeness* dataset of Winter and Grawunder (2012) and apply basic methods of multilevel modelling.

```
pacman::p_load(rstanarm, tidyverse, lmerTest, lme4)
pacman::p_load(MuMIn, effects)
```

### Dataset

The dataset has been shared on GitHub, so make sure that the csv-file is on your current path. Otherwise you can supply the full path.

```
politeness <- read.csv('politeness.csv') ## read in data
```

## Exercises and objectives

The objectives of the exercises of this assignment are:

- 1) Learning to recognize hierarchical structures within datasets and describing them
- 2) Creating simple multilevel models and assessing their fitness
- 3) Write up a report about the findings of the study

REMEMBER: In your report, make sure to include code that can reproduce the answers requested in the exercises below

REMEMBER: This assignment will be part of your final portfolio

### Exercise 1 - describing the dataset and making some initial plots

- 1) Describe the dataset, such that someone who happened upon this dataset could understand the variables and what they contain
  - i. Also consider whether any of the variables in *politeness* should be encoded as factors or have the factor encoding removed. Hint: `?factor`

```
summary(politeness)
```

```

```

- 2) Create a new data frame that just contains the subject *F1* and run two linear models; one that expresses *f0mn* as dependent on *scenario* as an integer; and one that expresses *f0mn* as dependent on *scenario* encoded as a factor

```
politeness_F1 <- politeness %>%
  filter(subject == "F1")
m1 <- lm(f0mn ~ scenario, data = politeness_F1, refresh = 0)
```

```
## Warning: In lm.fit(x, y, offset = offset, singular.ok = singular.ok, ...) :
## extra argument 'refresh' will be disregarded
```

```
m2 <- lm(f0mn ~ as.integer(scenario), data = politeness_F1, refresh = 0)
```

```
## Warning: In lm.fit(x, y, offset = offset, singular.ok = singular.ok, ...) :
## extra argument 'refresh' will be disregarded
```

- i. Include the model matrices,  $XX'$  from the General Linear Model, for these two models in your report and

## Scenario Encoded as Factor

```
#Design Matrix  
model.matrix(m1)
```

```
##      (Intercept) scenario2 scenario3 scenario4 scenario5 scenario6 scenario7  
## 1             1          0          0          0          0          0          0  
## 2             1          0          0          0          0          0          0  
## 3             1          1          0          0          0          0          0  
## 4             1          1          0          0          0          0          0  
## 5             1          0          1          0          0          0          0

```

The design matrix is a [14x7] matrix, so we will get the following  $\beta_{0-6}$ . This is also shown by the summary of a our linear regression model. A simple regression  $f0mn \sim \text{scenario}$  was conducted. Scenario seemed to account for 36.4% of the variance in  $f0mn$  following adjusted  $R^2$ .  $F(1,6) = 2.24$ ,  $p > 0.5$ ) all beta values were insignificant. We only have 14 observations spread out over 7 different levels. So the high p-value is most likely due to sample-size. A further power-analysis could show the required sample size required.

Now that scenario is encoded as an integer the design matrix will be a  $[14 \times 2]$  matrix. Our model will therefore only give us  $\beta_{0-1}$  and not a  $\beta$  for each level of scenario as done in the previous model. This model assumes that there is a constant increment of f0mn following a “increase” in scenario (if you can even talk about a unit increase of scenario). This would only make sense if scenarios were ordered as getting harder and harder. The model is again  $f0mn \sim \text{scenario}$   $F(1,12) = 2.231, p > 0.5$  with an adjusted  $R^2 = 0.0865$  showing an explained variance of 8.65% ( $\beta_1 = -6.886, SE = 4.6, t = -1.5, p > 0.16$ .) Again such a small sample size might be tricky to work with.

ii. Which coding of `_scenario_`, as a factor or not, is more fitting?

I would argue that scenario treated as a factor makes more sense. As mentioned a linear relationship between scenario number and f0mn does not make sense.

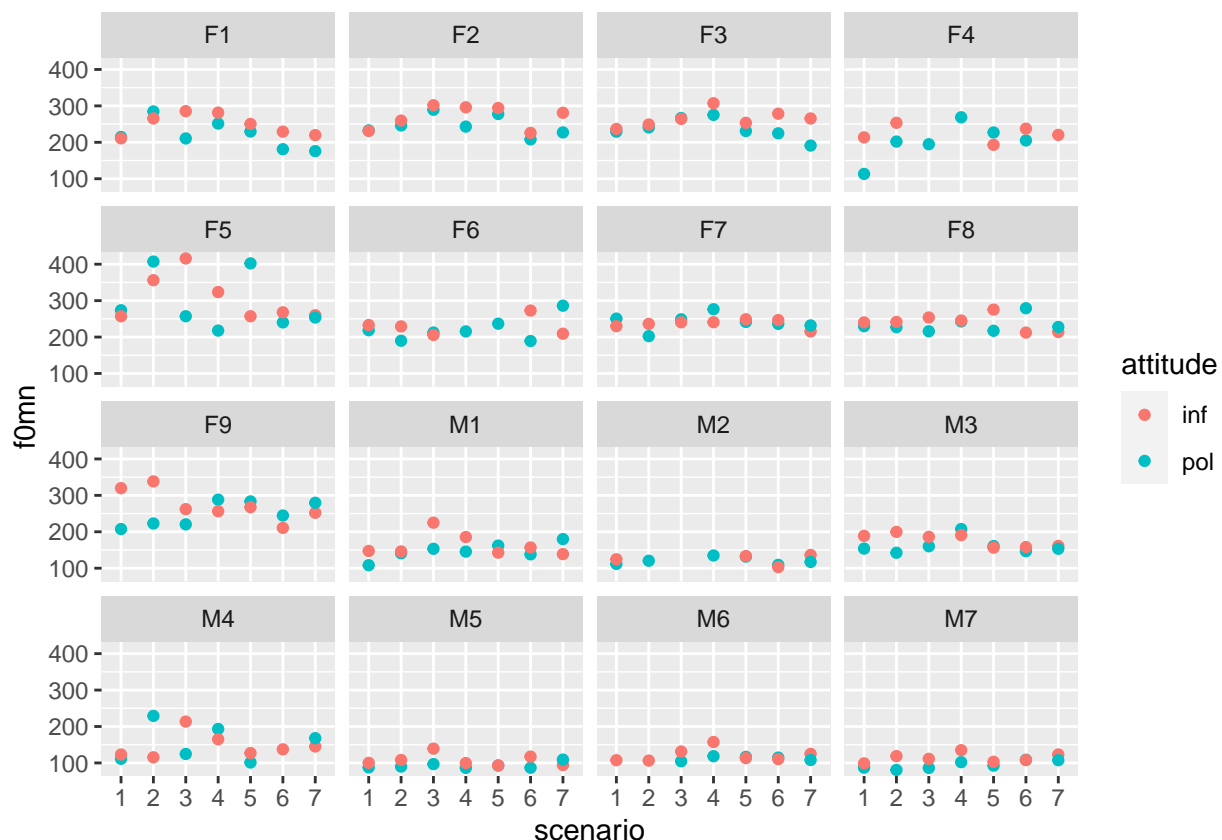

Scenario’s effect on f0mn in such a scenario as,  $\text{Scenario}[1] < \text{Scenario}[2] > \text{Scenario}[3]$ . Would not be possible to model having scenario as an integer.

3) Make a plot that includes a subplot for each subject that has *scenario* on the x-axis and *f0mn* on the y-axis and where points are colour coded according to *attitude*

i. Describe the differences between subjects

```
ggplot(politeness, aes(x = scenario, y = f0mn, colour = attitude)) + geom_point()+
  facet_wrap(~subject)
```

```
## Warning: Removed 12 rows containing missing values (geom_point).
```

There seem to be a lower baseline/intercept given that you’re a male. Attitude doesn’t seem to have an

large effect on *f0mn*. So an idea could be to add Gender as a fixed effect and subject as a random intercept as there is also individual variance within the gender category.

## Exercise 2 - comparison of models

For this part, make sure to have `lme4` installed.

You can install it using `install.packages("lme4")` and load it using `library(lme4)`

`lmer` is used for multilevel modelling

```
mixed.model <- lmer(f0mn ~ scenario + gender + (1|subject), data=politeness)
```

1) Build four models and do some comparisons

i. a single level model that models *f0mn* as dependent on *gender*

```
m3.1 <- lm(f0mn ~ gender, data = politeness)
```

ii. a two-level model that adds a second level on top of i. where unique intercepts are modelled for each scenario

```
m3.2 <- lmer(f0mn ~ gender + (1|scenario), data = politeness, REML = F)
```

iii. a two-level model that only has `_subject_` as an intercept

```
m3.3 <- lmer(f0mn ~ gender + (1|subject), data = politeness, REML = F)
```

iv. a two-level model that models intercepts for both `_scenario_` and `_subject_`

```
m3.4 <- lmer(f0mn ~ (1|scenario) + (1|subject), data = politeness, REML = F)
```

v. which of the models has the lowest residual standard deviation, also compare the Akaike Information Criterion

```
#Calculate Residual Standard Deviation
c(S_res1 = sqrt(sum(resid(m3.1)^2)/(nrow(politeness)-2)),
  S_res2 = sqrt(sum(resid(m3.2)^2)/(nrow(politeness)-2)),
  S_res3 = sqrt(sum(resid(m3.3)^2)/(nrow(politeness)-2)),
  S_res4 = sqrt(sum(resid(m3.4)^2)/(nrow(politeness)-2)))
```

```
##      S_res1      S_res2      S_res3      S_res4
## 38.38130 37.10991 30.27006 28.50493
```

```
#Compare AIC
AIC(m3.1,m3.2,m3.3,m3.4)
```

```
##      df      AIC
## m3.1  3 2163.971
## m3.2  4 2162.257
## m3.3  4 2112.048
## m3.4  4 2133.226
```

m3.4 is the model with the lowest residual standard deviation and also performs the best following the AIC.

vi. which of the second-level effects explains the most variance?

```
#Anova cannot compare multi-level and single-level models. :(
anova(m3.2,m3.3,m3.4)
```

```
## Data: politeness
## Models:
## m3.2: f0mn ~ gender + (1 | scenario)
## m3.3: f0mn ~ gender + (1 | subject)
## m3.4: f0mn ~ (1 | scenario) + (1 | subject)
##      npar    AIC    BIC logLik deviance  Chisq Df Pr(>Chisq)
## m3.2     4 2162.3 2175.7 -1077.1   2154.3
## m3.3     4 2112.1 2125.5 -1052.0   2104.1 50.209  0
## m3.4     4 2133.2 2146.7 -1062.6   2125.2  0.000  0
```

```
#Look for varaince explained
MuMIn::r.squaredGLMM(m3.2)
```

```
## Warning: 'r.squaredGLMM' now calculates a revised statistic. See the help page.
```

```
##           R2m          R2c
## [1,] 0.6817304 0.6965456
```

```
MuMIn::r.squaredGLMM(m3.3)
```

```
##           R2m          R2c
## [1,] 0.6798832 0.7862932
```

```
MuMIn::r.squaredGLMM(m3.4)
```

```
##           R2m          R2c
## [1,]    0 0.8045275
```

M3.2 (f0mn ~ gender + (1|scenario)) showed the best variance explained purely by fixed effects. But m3.4 (f0mn ~ gender + (1|scenario) + (1|subject)) showed most explained variance with 80% of the variance being accounted for from both fixed and random effects.

We can also conclude that adding subject as random intercept rather than scenario explains more of the variance but also has more shared variance with our fixed effect gender.

2) Why is our single-level model bad?

- i. create a new data frame that has three variables, *subject*, *gender* and *f0mn*, where *f0mn* is the average of all responses of each subject, i.e. averaging across *attitude* and *\_scenario\_*

```

politeness_sel <- politeness %>%
  filter(!is.na(f0mn)) %>%
  group_by(subject) %>%
  summarise(f0mn = mean(f0mn))

politeness_sel <- politeness_sel %>%
  mutate(gender = if_else(grepl("F", politeness_sel$subject, ignore.case = T), "F", "M")) %>%
  mutate(gender = as.factor(gender))

```

ii. build a single-level model that models `_f0mn_` as dependent on `_gender_` using this new dataset

```

m4.1 <- lm(f0mn ~ gender, data = politeness_sel)

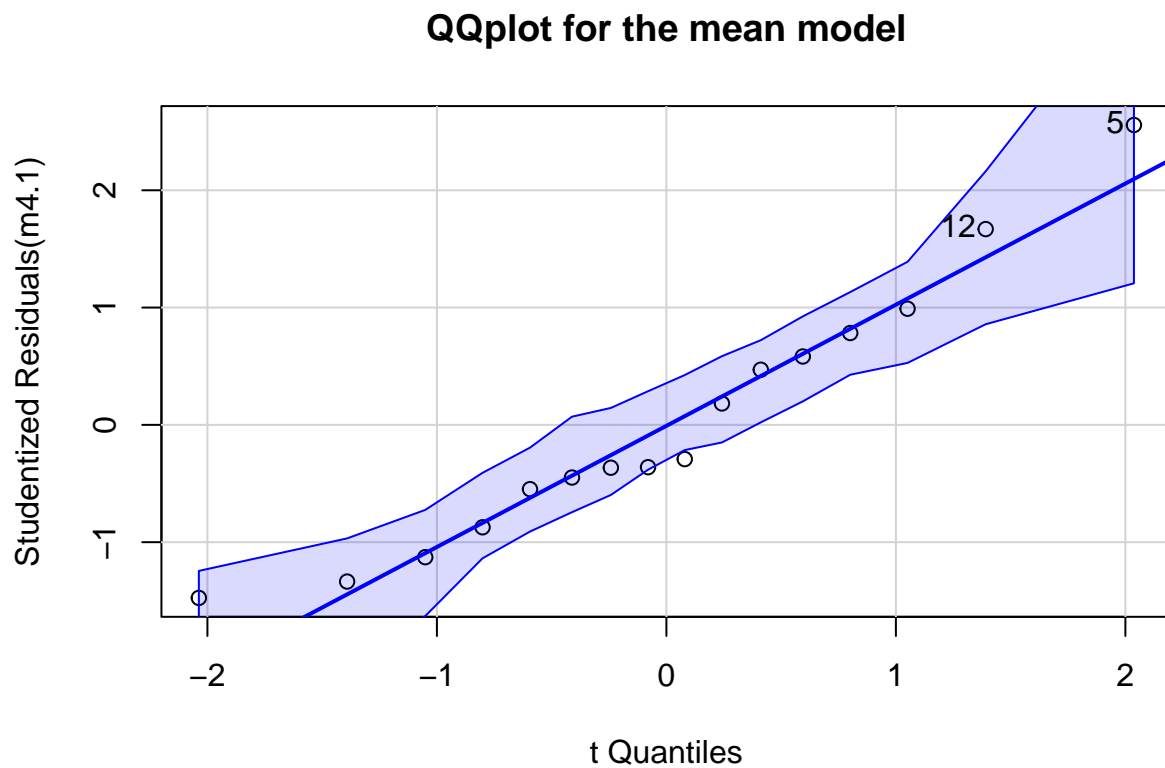

```

iii. make Quantile-Quantile plots, comparing theoretical quantiles to the sample quantiles) using `'qqnorm'`

```

#qqPlot
car::qqPlot(m4.1, main = "QQplot for the mean model")

```

```
## [1] 5 12
```

```

car::qqPlot(m3.1, main = "QQplot for the normal model")

```

## QQplot for the normal model

```
## [1] 59 62
```

Both models residual distribution seems to be slightly heavy tailed. This could be solved with a simple yuen trim of outliers. The first model 3.1 holds the assumptions for the GLM better than the new model where `f0mn` is averaged.

iv. Also make a quantile-quantile plot for the residuals of the multilevel model with two intercepts. 1

```
#car::qqPlot doesn't like mixed effect models so we do it like this.  
qqnorm(resid(m3.4))  
qqline(resid(m3.4))
```

## Normal Q-Q Plot

3) Plotting the two-intercepts model

m3.4

```
## Linear mixed model fit by maximum likelihood ['lmerModLmerTest']
## Formula: f0mn ~ (1 | scenario) + (1 | subject)
## Data: politeness
##      AIC      BIC    logLik deviance df.resid
## 2133.227 2146.653 -1062.613  2125.227     208
## Random effects:
## Groups   Name      Std.Dev.

i. Create a plot for each subject, (similar to part 3 in Exercise 1), this time also indicating the fit

```

politeness_fil <- politeness %>% #Remove NA's
  filter(!is.na(f0mn))

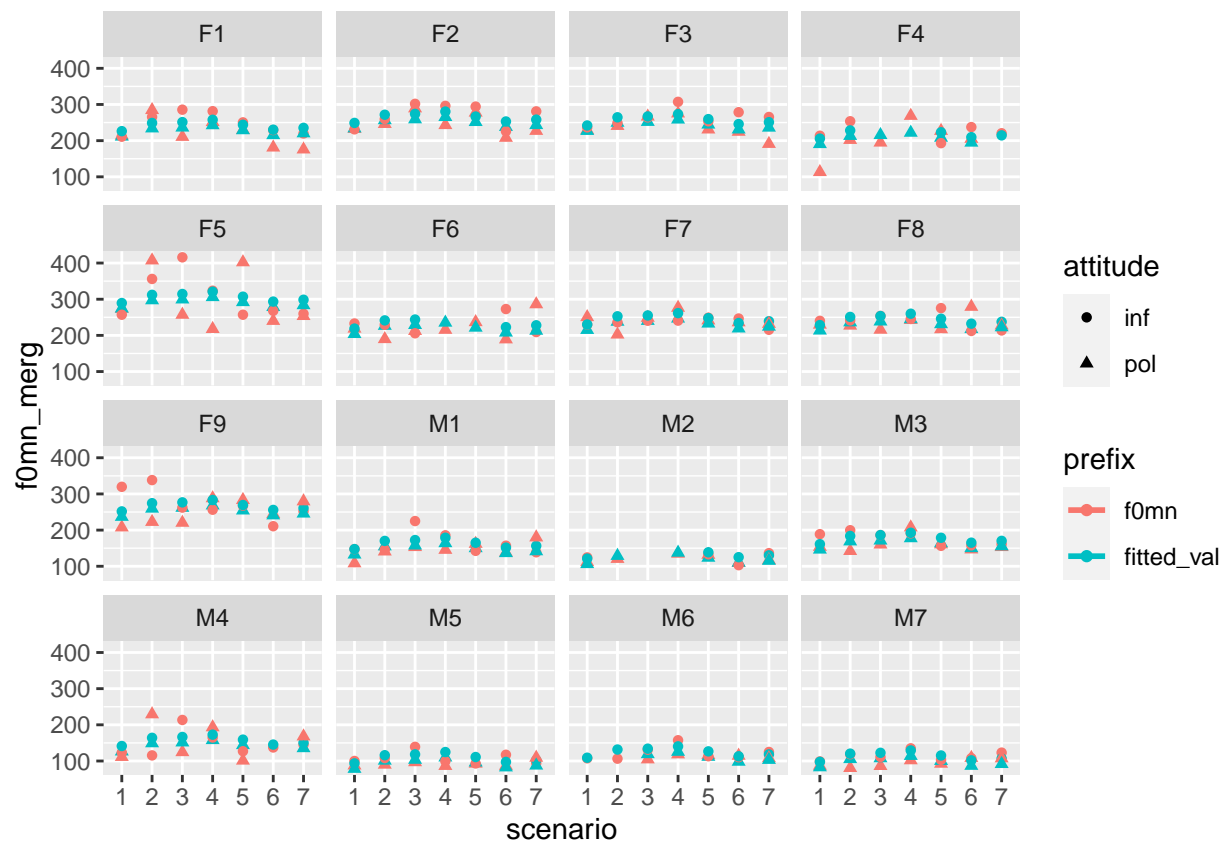

m3.5<- lmer(f0mn ~ scenario + attitude + (1|subject), data = politeness_fil)#new fit

politeness_fit <- politeness_fil %>% #Create data frame with fitted and actual values.
  mutate(fitted_val = fitted.values(m3.5)) %>%
  pivot_longer(cols = c(f0mn,fitted_val) , names_to = "prefix", values_to = "f0mn_merg")

ggplot(politeness_fit, aes(x = scenario, y = f0mn_merg, colour = prefix, shape = attitude)) + geom_point()

## 'geom_smooth()' using formula 'y ~ x'

```

### Exercise 3 - now with attitude

1) Carry on with the model with the two unique intercepts fitted (*scenario* and *subject*).

i. now build a model that has *attitude* as a main effect besides *gender*

```
m5.1 <- lmer(f0mn ~ attitude + gender + (1|subject) + (1|scenario), data = politeness, REML = F)
```

ii. make a separate model that besides the main effects of *\_attitude\_* and *\_gender\_* also include their interaction

```
m5.2 <- lmer(f0mn ~ attitude*gender + (1|subject) + (1|scenario), data = politeness, REML = F)
```

iii. describe what the interaction term in the model says about Korean men's pitch when they are polite

```

The model  $f0mn \sim \text{attitude:gender} + (1|\text{subject}) + (1|\text{scenario})$  has an  $R^2c$  0.81 both attitude and gender showed a significant effect on  $f0mn$  ( $\beta_1(\text{attitude\_pol}) = -17.2$ ,  $SE = 5.4$ ,  $p > 0.05$ ) and ( $\beta_2(\text{genderM}) = -119$ ,  $SE = 12.8$ ,  $p > 0.05$ ). Being polite and male lowers your frequency. Being both Male and Polite has an interaction effect of ( $\beta_3 = 5.5$ ,  $SE = 8.24$ ,  $p < 0.05$ ). Hereby concluding that there is a small positive insignificant interaction effect of being male and polite. The SE being proportional large compared to the effect size makes it very difficult to say anything meaningful.

- 2) Compare the three models (1. gender as a main effect; 2. gender and attitude as main effects; 3. gender and attitude as main effects and the interaction between them. For all three models model unique intercepts for *subject* and *scenario*) using residual variance, residual standard deviation and AIC.

```

#residual variance

3) Choose the model that you think describe the data the best - and write a short report on the main findings based on this model. At least include the following:

- i. describe what the dataset consists of
- ii. what can you conclude about the effect of gender and attitude on pitch (if anything)?
- iii. motivate why you would include separate intercepts for subjects and scenarios (if you think they should be included)
- iv. describe the variance components of the second level (if any)
- v. include a Quantile-Quantile plot of your chosen model

## My answer to all of the above

I have selected the model 5.1 ( $f0mn \sim \text{gender} + \text{attitude} + (1|\text{subject}) + (1|\text{scenario})$ ) My decision is based primary based on AIC  $R_{\text{res}}$  and RS. But theoretically it also makes sense to include both random intercepts due to the study being repeated measure and some variance being random/unsystematic. attitude furthermore seems like an important addition to the model as specific attitudes are correlated with pitch

frequency (See imaginiry study). However the interaction between gender:attitude doesn't add anything explaining to the model.

“We used R (R Core Team, 2019) and lmerTest (Kuznetsova, Brockhoff and Christensen, 2017) to perform a linear mixed effects analysis of the relationship between f0mn, gender and attitude. As random effects, we had intercepts for subjects, and scenario.

Both fixed and random effects accounted for roughly 82% of the variance in the f0mn variable with random effects proportion being 12.7%. Visual inspection shows that both the qqplot and histogram violates the assumption of a mixed effect linear model. The more robust generalized mixed effect model with a link function would be preferred. But as did was not the task such model was not constructed.

f0mn was found to be significantly modulated by gender.  $\beta_2 = -115, SE = 12.16, p < 0.05$  Attitude also showed a significant modulating of f0mn  $\beta_1 = -14.8, SE = 4, p < 0.05$
